A genetic interaction is a functional relationship between 2 genes

Genes A and B genetically interact when:

simultaneous perturbation  
 $\neq$   
combination of individual effects.

# Genetic interactions help map gene function

# Large scale quantitative mapping has become possible

Synthetic Genetic Array (SGA) technique [Costanzo 2010]

- 5.4 millions gene-gene pairs tested (~30% of all pairs)
- genetic interaction profiles for ~75% of the yeast genes

*Other techniques: dSLAM [Pan 2006], GIM [Decourty 2008], E-MAP [Schuldiner 2005]*

*Other species: S. pombe, E. coli, C. elegans, mammalian cell culture*

# Clustering this data shows monochromatic patterns

Monochromatic red connection

*Interaction matrix*

Vacuolar  
ATPase

*Interaction network*

Retrograde  
transport

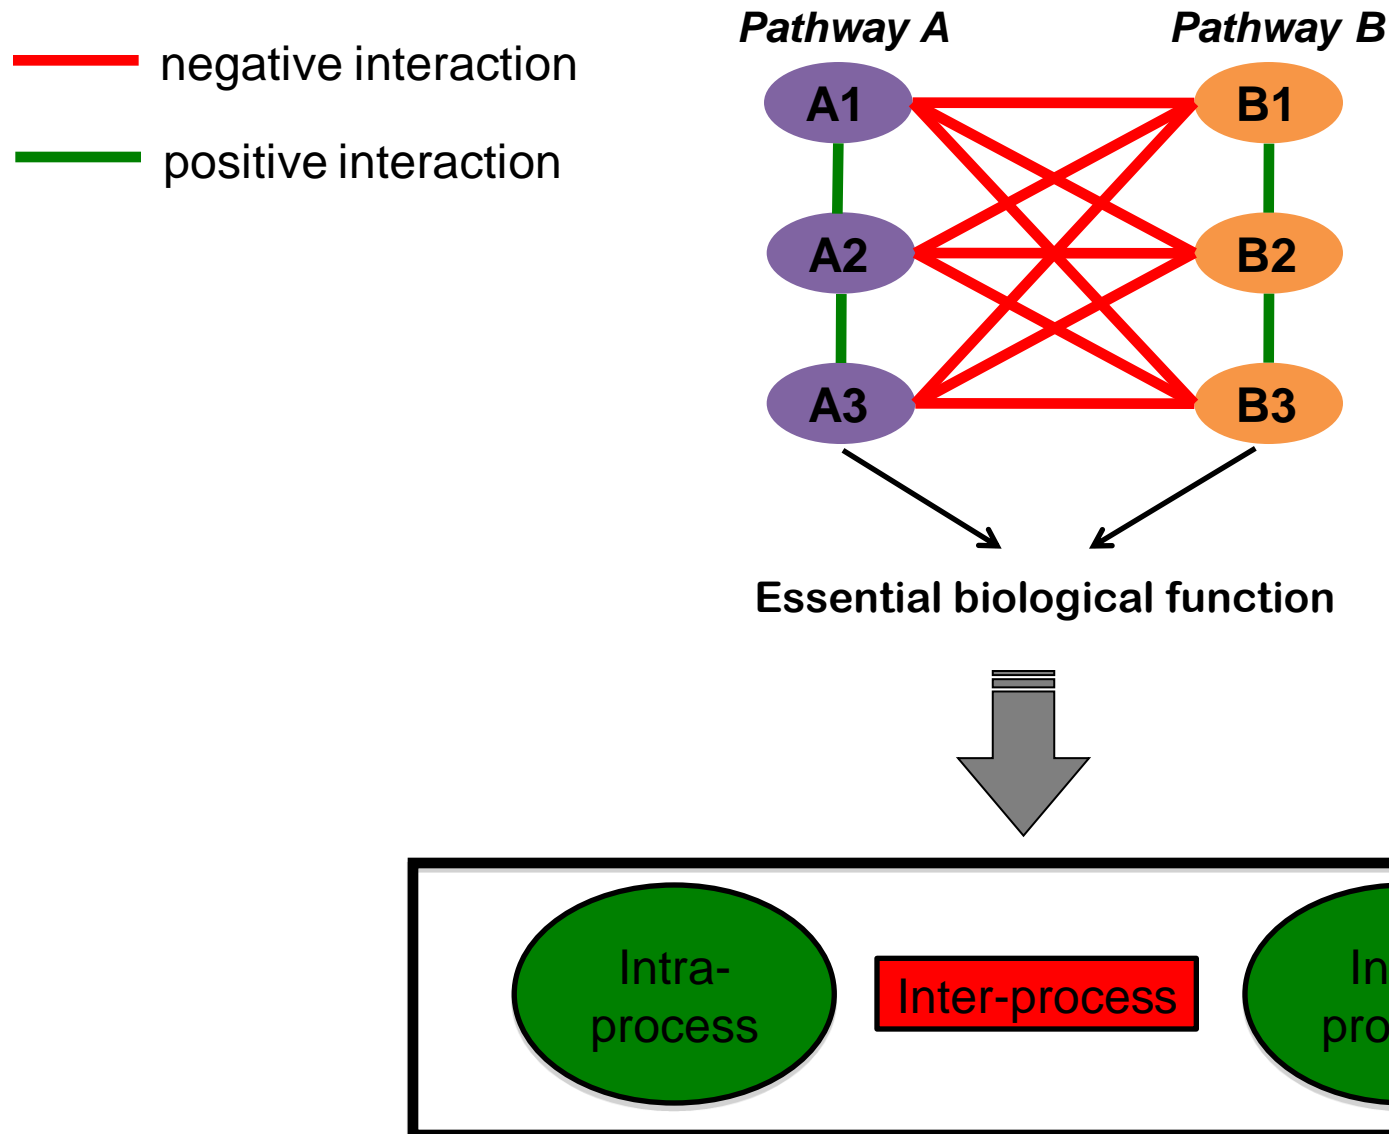

Monochromatic green processes

Vacuolar  
ATPase

— negative  
— positive

Current model states that these monochromatic patterns identify pathways and complexes

But recent results suggest the model has to be revisited

- Protein **complexes** with essential genes tend to be monochromatic **red** [Bandyopadhyay *et al.*, 2008]
- Many **connections** between biological processes tend to be monochromatic **green** [Costanzo *et al.*, 2010]

Does it hold for all biological processes and their connections?

Known biological processes  
*from Gene Ontology*

# We systematically evaluated the monochromatic patterns for known biological processes

17,595  
processes in GO  
2,917  
for yeast  
1,377  
with  
SGA interactions  
566  
with good  
SGA coverage

$$Score = \frac{\sum sga}{\sum |sga|}$$

Random networks  
shuffle labels

$$Z-score = \frac{Score - \mu}{\sigma}$$

Biological process  
(GO term)

All red -> Score = -1  
All green -> Score = +1

10% of yeast biological processes are monochromatic

566 processes covered  
by SGA data

## 50 monochromatic processes

- 45 negative
- 5 positive

## Histone exchange

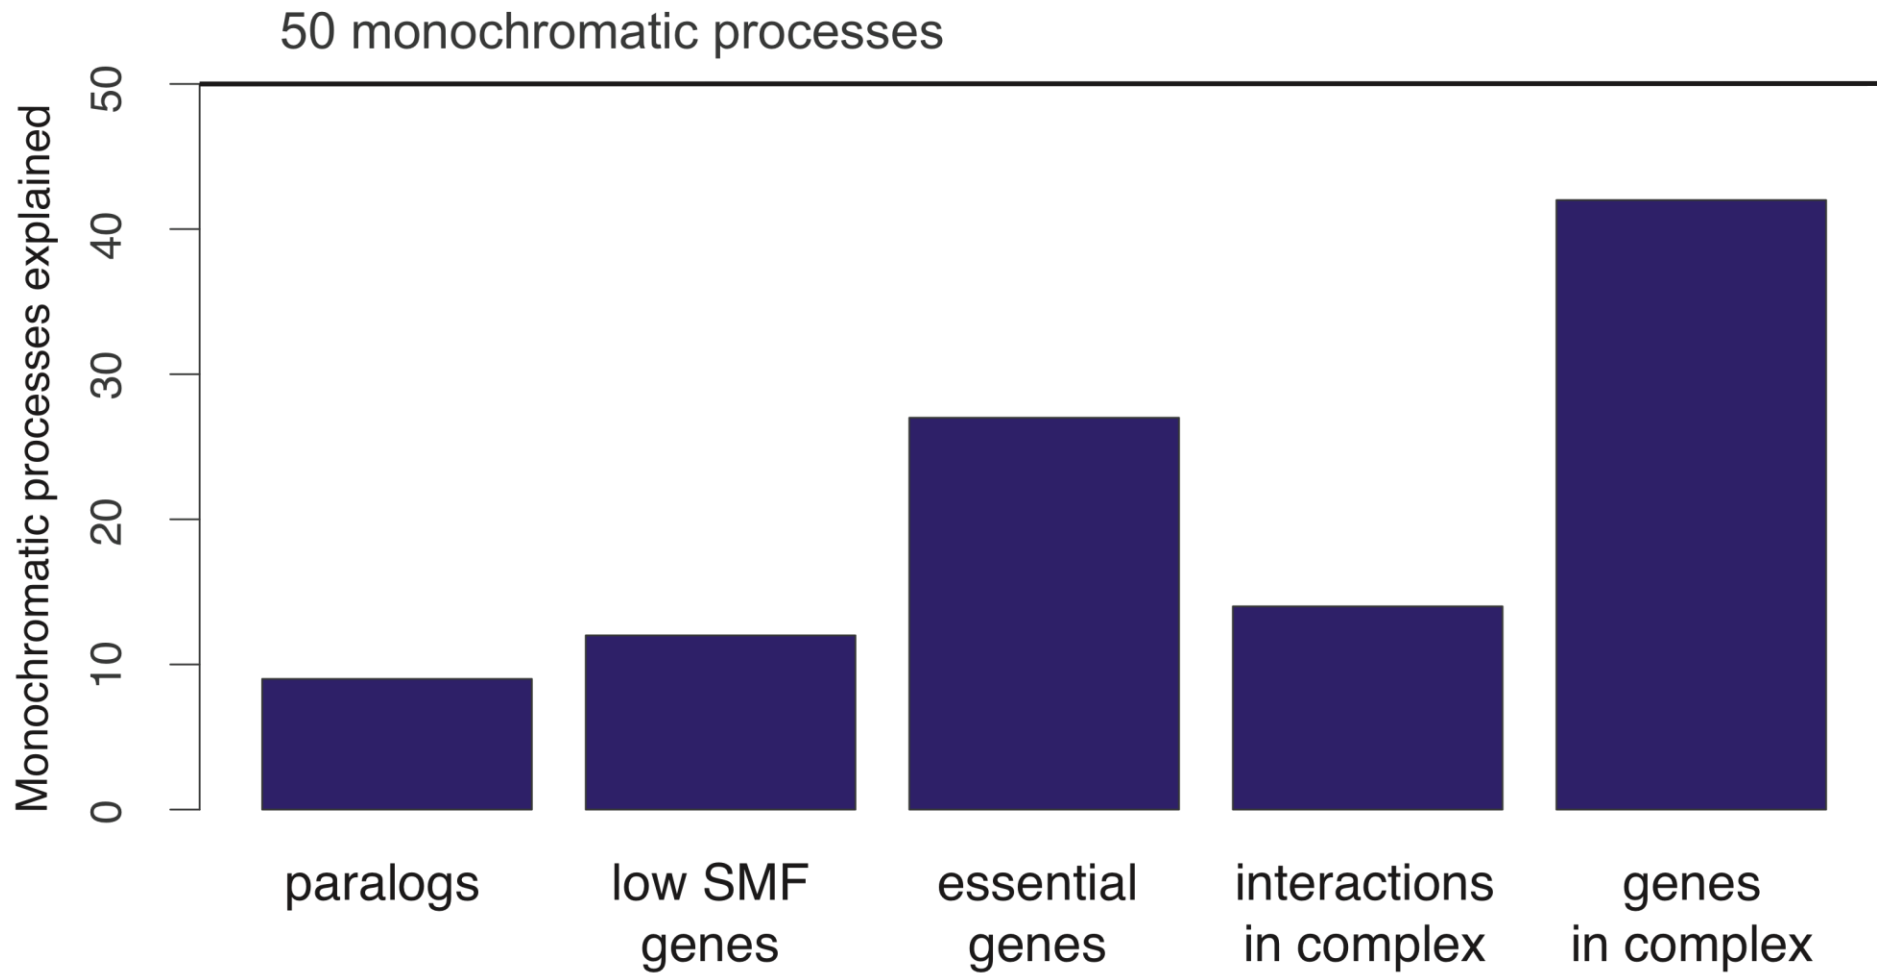

## Protein import

# Protein complexes play a major role in these patterns

- We remove protein complexes and assess monochromatic patterns again

### Mitotic sister chromatid cohesion

Monochromatic green  
connection

614 positive  
773 negative

mainly due to complexes

# Interactions are biased towards protein complexes

Gene in a **complex**

Gene **not** in any **complex**

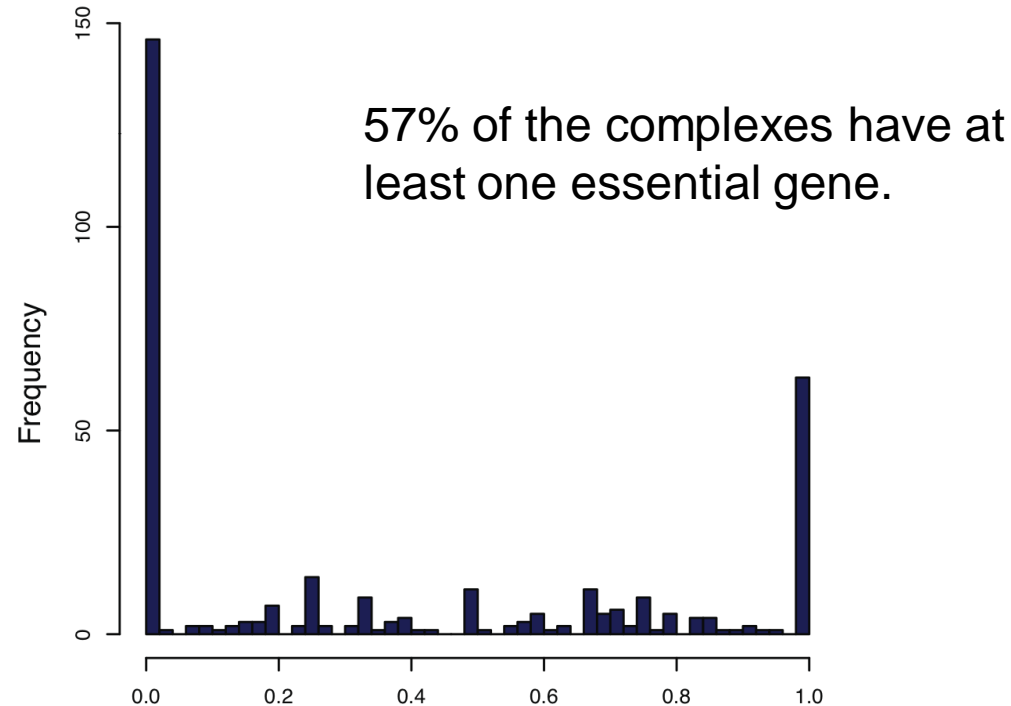

|                       | Complex         | No complex      |
|-----------------------|-----------------|-----------------|
| Tested interactions   | 2,801,630 (49%) | 2,898,509 (51%) |
| Observed interactions | 119,871 (63%)   | 70,125 (37%)    |

*Fisher test p-value < 10<sup>-5</sup>*

Genes encoding proteins in complexes are more likely to genetically interact than genes encoding proteins not in any complex.

# Most complexes are essential for yeast growth

|                    | In complex  | Not in complex |
|--------------------|-------------|----------------|
| Essential gene     | 684 (61%)   | 438 (39%)      |
| Non essential gene | 1,111 (20%) | 4,378 (80%)    |

*Fisher test p-value ~ 0*

Essential genes tend to be in protein complexes.

# Concluding remarks

- Systematic study of the monochromatic nature of biological processes and their connections
  - ~10% of processes are monochromatic in SGA
  - Monochromatic connections are rare (~1%)
- Revisited model of the genetic landscape in yeast
  - Both monochromatic negative and positive processes
  - Both monochromatic negative and positive connections between processes
  - Protein complexes explain most of the patterns
  - Genetic interactions are biased towards protein complexes
  - Complexes are essential for yeast growth
- Mapped monochromatic processes and their connections in cell growth in yeast

# This hierarchical and modular monochromatic map of sensitive and redundant biological systems...

- ... can an help
  - Understand the organization of sensitive and redundant biological systems
  - Unravel anti-cancer therapy
  - Predict drug synergy
- ... has to be explored
  - For other species
  - For other conditions

# first European Student Council Symposium

<http://escs.iscbssc.org>

## Program

- keynote Yves Van de Peer
- 4 student presentations
- poster session
- workshop « Presenting Science using the theatre approach »

### ▪ Registered to ECCB?

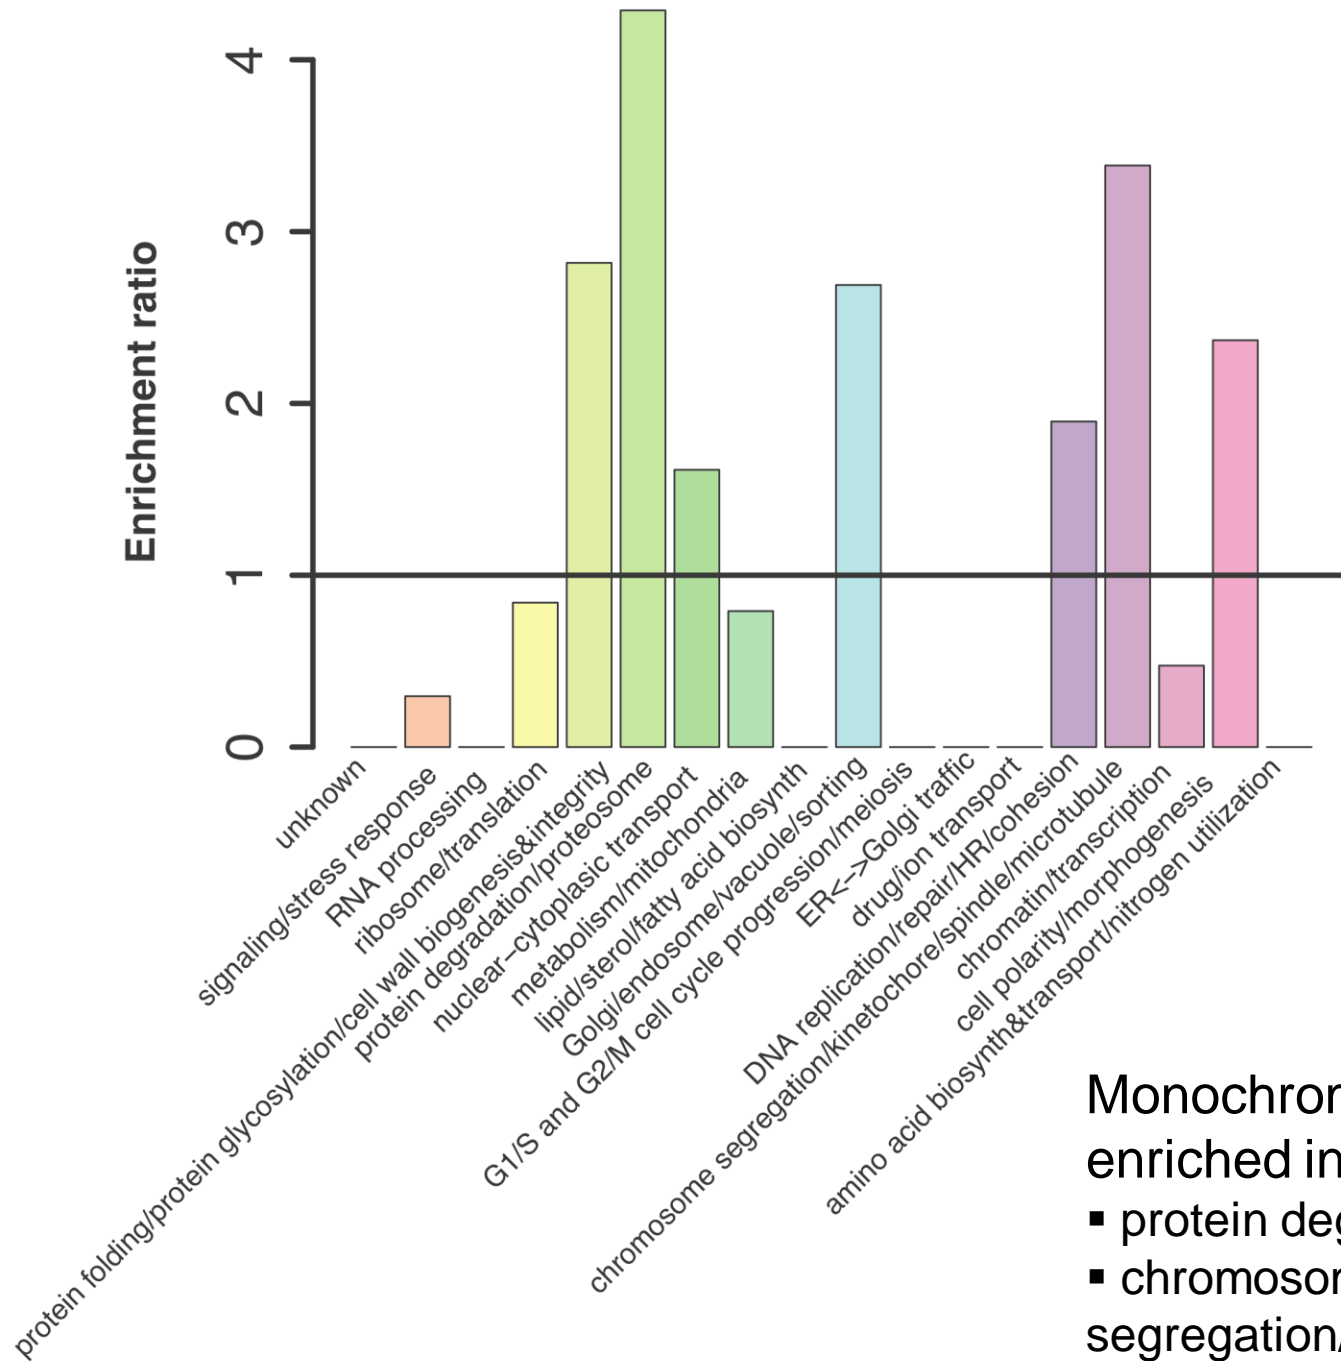

- *You can still add it to the registration*

### ▪ Not registered to ECCB?

- *You can attend the symposium only*

- Sept 26th
- ECCB satellite
- Ghent, Belgium
- 100 euros

Sign up now! 😊

Monochromatic processes are enriched in:

- protein degradation/proteasome
- chromosome segregation/microtubule

# The result holds for different coverage cutoffs

| Coverage cutoff | Covered processes | Monochromatic processes | Ratio (%) |
|-----------------|-------------------|-------------------------|-----------|
| 0               | 1031              | 68                      | 6.6       |
| 0.2             | 1019              | 68                      | 6.7       |
| 0.4             | 833               | 66                      | 7.9       |
| 0.6             | 566               | 50                      | 8.8       |
| 0.8             | 99                | 9                       | 9.0       |
| 1               | 25                | 2                       | 8.0       |

# The various features are overlapping

# Saturation tests indicate that 350 iterations is enough
