Molecular barcodes for soil nematode identification

ROBIN FLOYD, EYUALEM ABEBE, ARTEMIS PAPERT and MARK BLAXTER
Institute of Cell, Animal and Population Biology, University of Edinburgh, Edinburgh EH9 3JT, UK

Abstract

Using a molecular barcode, derived from single-specimen polymerase chain reaction (PCR) and sequencing of the 5' segment of the small subunit ribosomal RNA (SSU) gene, we have developed a molecular operational taxonomic unit (MOTU) scheme for soil nematodes. Individual specimens were considered to belong to the same MOTU when the sequenced segment of 450 bases was > 99.5% identical. A Scottish upland *Agrostis-Festuca* grassland soil was sampled, using both culture-based and random selection methods. One hundred and sixty-six cultured isolates were sequenced, and clustered into five MOTU. From 74 randomly sampled individuals across the study site, 19 MOTU were defined. A subsequent sample of 18 individuals from a single subplot contained eight MOTU, four of which were unique to the single subplot sample. Interestingly, seven of these MOTU were not present in the culture-independent sampling. Overall, a total of 23 MOTU were defined from only 240 sequences. Many MOTU could readily be assigned to classical, morphologically defined taxonomic units using a database of SSU sequences from named nematode species. The MOTU technique allows a rapid assessment of nematode taxon diversity in soils. Correlation with a database of sequences from known species offers a route to application of the technique in ecological surveys addressing biological as well as genetic diversity.

Keywords: biodiversity assessment, DNA sequence, nematodes, 18S ribosomal RNA (SSU)

Biological identifications through DNA barcodes

Paul D. N. Hebert*, Alina Cywinska, Shelley L. Ball
and Jeremy R. deWaard

Department of Zoology, University of Guelph, Guelph, Ontario N1G 2W1, Canada

Although much biological research depends upon species diagnoses, taxonomic expertise is collapsing. We are convinced that the sole prospect for a sustainable identification capability lies in the construction of systems that employ DNA sequences as taxon ‘barcodes’. We establish that the mitochondrial gene cytochrome *c* oxidase I (COI) can serve as the core of a global bioidentification system for animals. First, we demonstrate that COI profiles, derived from the low-density sampling of higher taxonomic categories, ordinarily assign newly analysed taxa to the appropriate phylum or order. Second, we demonstrate that species-level assignments can be obtained by creating comprehensive COI profiles. A model COI profile, based upon the analysis of a single individual from each of 200 closely allied species of lepidopterans, was 100% successful in correctly identifying subsequent specimens. When fully developed, a COI identification system will provide a reliable, cost-effective and accessible solution to the current problem of species identification. Its assembly will also generate important new insights into the diversification of life and the rules of molecular evolution.

Abstract

So-called DNA barcodes have recently been proposed to answer the problem of specimen identification and to quantify global biodiversity. We show that this proposition is wanting in terms of rationale, methodology and interpretation of results. In addition to falling short of all its stated goals, the method abandons the benefits of morphological studies in favor of a limited molecular identification system that would ultimately impede our understanding of biodiversity.

New . . . but not good.

- **unjustified emphasis/reliance on DNA data**
- **the incorrect analogy to Universal Product Codes (UPC):** typological thinking is not really new.
- **the concerted effort,** but largely to do the wrong thing

DNA barcoding: definitions

- **DNA barcoding *sensu stricto***: identification of the species level using a single standardized DNA fragment; (= CBoL view)
- **DNA barcoding *sensu lato***: identification of any taxonomical level using any DNA fragment

Valentini A, Pompanon F, Taberlet P (2009) DNA barcoding for ecologists. *Trends in Ecology & Evolution*, **24**, 110-117.

The ideal DNA barcoding marker

- **Variability**: the gene region sequenced should be nearly identical among individuals of the same species, but different between species
- **Standardization**: the same DNA region used for different taxonomic groups
- **Phylogenetic information**: to easily assign unknown or not yet "barcoded" species to their taxonomic group (genus, family, etc.)
- **Robustness**: highly conserved priming sites, and highly reliable DNA amplifications and sequencing
- **Shortness**: amplification of degraded DNA

An *In silico* approach for the evaluation of DNA barcodes

Gentile Francesco Ficetola^{1,2,3*†}, Eric Coissac^{1*†}, Stéphanie Zundel¹, Tiayba Riaz¹, Wasim Shehzad¹, Julien Bessière¹, Pierre Taberlet¹, François Pompanon¹

(2010) *BMC Genomics*, **11**, 434.

Abstract

Background: DNA barcoding is a key tool for assessing biodiversity in both taxonomic and environmental studies. Essential features of barcodes include their applicability to a wide spectrum of taxa and their ability to identify even closely related species. Several DNA regions have been proposed as barcodes and the region selected strongly influences the output of a study. However, formal comparisons between barcodes remained limited until now. Here we present a standard method for evaluating barcode quality, based on the use of a new bioinformatic tool that performs *in silico* PCR over large databases. We illustrate this approach by comparing the taxonomic coverage and the resolution of several DNA regions already proposed for the barcoding of vertebrates. To assess the relationship between *in silico* and *in vitro* PCR, we also developed specific primers amplifying different species of Felidae, and we tested them using both kinds of PCR.

Results: Tests on specific primers confirmed the correspondence between *in silico* and *in vitro* PCR. Nevertheless, results of *in silico* and *in vitro* PCRs can be somehow different, also because tuning PCR conditions can increase the performance of primers with limited taxonomic coverage. The *in silico* evaluation of DNA barcodes showed a strong variation of taxonomic coverage (i.e., universality): barcodes based on highly degenerated primers and those corresponding to the conserved region of the *Cyt-b* showed the highest coverage. As expected, longer barcodes had a better resolution than shorter ones, which are however more convenient for ecological studies analysing environmental samples.

Conclusions: *In silico* PCR could be used to improve the performance of a study, by allowing the preliminary comparison of several DNA regions in order to identify the most appropriate barcode depending on the study aims.

ITS as an environmental DNA barcode for fungi: an *in silico* approach reveals potential PCR biases

Eva Bellemain*¹, Tor Carlsen², Christian Brochmann¹, Eric Coissac³, Pierre Taberlet³ and Håvard Kauserud²

(2010) *BMC Microbiology*, **10**, 189.

Abstract

Background: During the last 15 years the internal transcribed spacer (ITS) of nuclear DNA has been used as a target for analyzing fungal diversity in environmental samples, and has recently been selected as the standard marker for fungal DNA barcoding. In this study we explored the potential amplification biases that various commonly utilized ITS primers might introduce during amplification of different parts of the ITS region in samples containing mixed templates ('environmental barcoding'). We performed *in silico* PCR analyses with commonly used primer combinations using various ITS datasets obtained from public databases as templates.

Results: Some of the ITS primers, such as ITS1-F, were hampered with a high proportion of mismatches relative to the target sequences, and most of them appeared to introduce taxonomic biases during PCR. Some primers, e.g. ITS1-F, ITS1 and ITS5, were biased towards amplification of basidiomycetes, whereas others, e.g. ITS2, ITS3 and ITS4, were biased towards ascomycetes. The assumed basidiomycete-specific primer ITS4-B only amplified a minor proportion of basidiomycete ITS sequences, even under relaxed PCR conditions. Due to systematic length differences in the ITS2 region as well as the entire ITS, we found that ascomycetes will more easily amplify than basidiomycetes using these regions as targets. This bias can be avoided by using primers amplifying ITS1 only, but this would imply preferential amplification of 'non-dikarya' fungi.

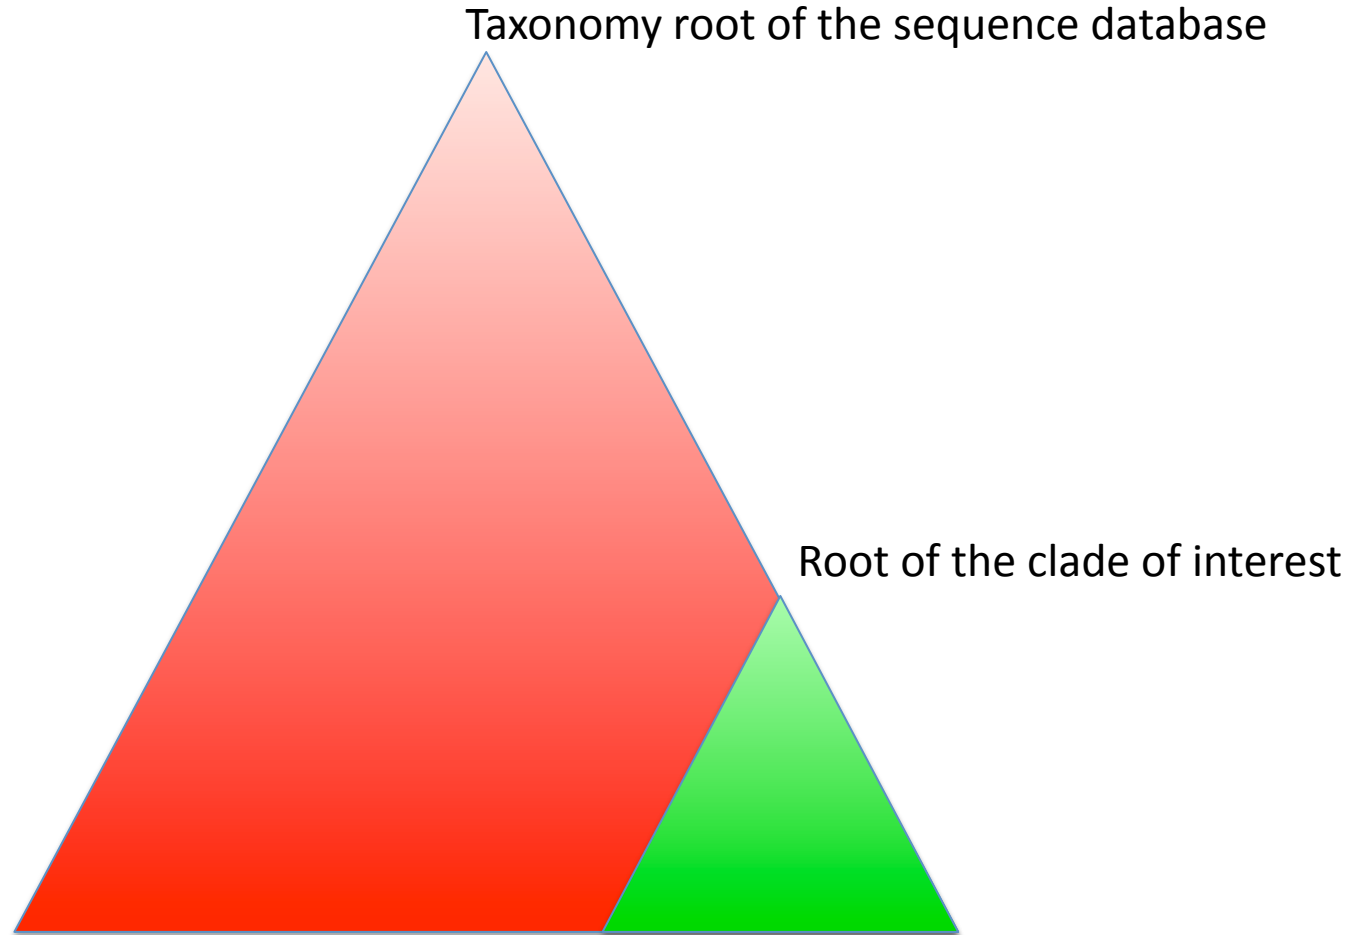

Conclusions: We conclude that ITS primers have to be selected carefully, especially when used for high-throughput sequencing of environmental samples. We suggest that different primer combinations or different parts of the ITS region should be analyzed in parallel, or that alternative ITS primers should be searched for.

Abstract

The development of DNA barcoding (species identification using a standardized DNA sequence), and the availability of recent DNA sequencing techniques offer new possibilities in diet analysis. DNA fragments shorter than 100–150 bp remain in a much higher proportion in degraded DNA samples and can be recovered from faeces. As a consequence, by using universal primers that amplify a very short but informative DNA fragment, it is possible to reliably identify the plant taxon that has been eaten. According to our experience and using this identification system, about 50% of the taxa can be identified to species using the *trnL* approach, that is, using the P6 loop of the chloroplast *trnL* (UAA) intron. We demonstrated that this new method is fast, simple to implement, and very robust. It can be applied for diet analyses of a wide range of phytophagous species at large scales. We also demonstrated that our approach is efficient for mammals, birds, insects and molluscs. This method opens new perspectives in ecology, not only by allowing large-scale studies on diet, but also by enhancing studies on resource partitioning among competing species, and describing food webs in ecosystems.

The *trnL* database for Arctic plant species

- 842 species was successfully sequenced for the *trnL* intron
- 709 species were sequenced twice or more
- 33.5% of the species and 77.1% of the genera could be identified by the P6 loop
- Low resolution in Salicaceae (*Salix* sp.), in Cyperaceae (*Carex* sp.), in Asteraceae, and in Poaceae.

TECHNICAL ADVANCES

Using next-generation sequencing for molecular reconstruction of past Arctic vegetation and climate

New ITS1 barcode primers for Asteraceae, Poaceae, and Cyperaceae

- Asteraceae

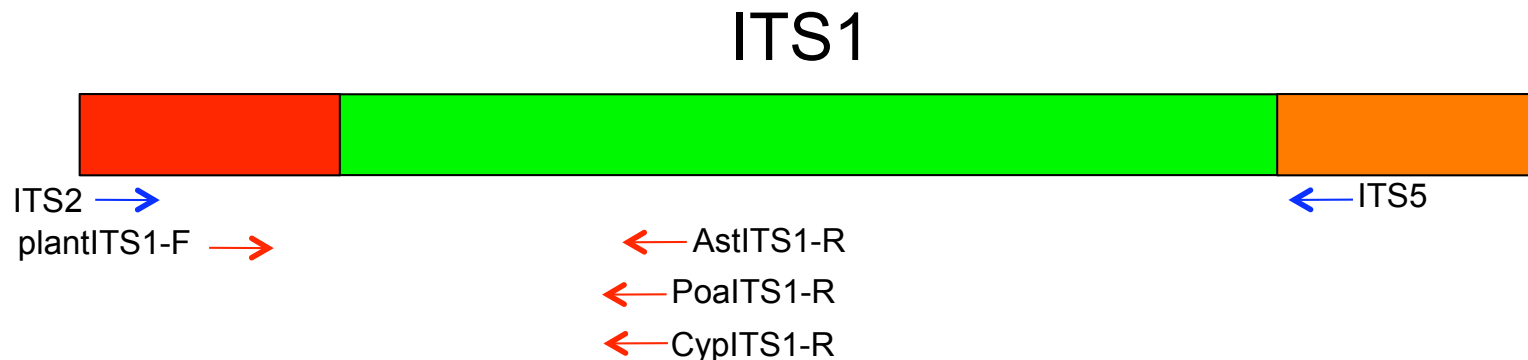

- plantITS1-F: 5'-GATATCCGTTGCCGAGAGTC-3'; AstITS1-R: 5'-CGGCACGGCATGTGCCAAGG-3'
- Length: less than 90bp; 68% Asteraceae with a maximum of 2 mismatches

- Poaceae

- plantITS1-F: 5'-GATATCCGTTGCCGAGAGTC-3'; PoalITS1-R: 5'-CCGAAGGCGTCAAGGAACAC-3'
- Length: 54bp to 88bp; 98.5% Poaceae with a maximum of 2 mismatches

- Cyperaceae

- plantITS1-F: 5'-GATATCCGTTGCCGAGAGTC-3'; CypITS1-R: 5'-GGATGACGCCAAGGAACAC-3'
- Length: 46bp to 78bp; 93% Cyperaceae with a maximum of 2 mismatches

Biodiversity and DNA barcoding

- The DNA barcoding concept
- Our scientific objectives
- New sequencing technologies
- Bioinformatic aspects
 - The challenges
 - Available programs for preparing the experiments
 - Available programs for analyzing the output of next generation sequencers
- High throughput plant identification
- **High throughput animal identification**
- Conclusion

Diet analysis of carnivores

- Technically more difficult than when analyzing herbivore diet
- How to amplify the prey DNA, without amplifying host DNA when using universal primers?
- Possibility of using a blocking primer for host DNA during the amplification

Experimental protocol

- Sampling in the field
- DNA extraction
- DNA amplification
 - with mtDNA 12S universal primers 
 - with and without blocking primer 

- DNA sequencing on a next generation sequencer (either 454 or Solexa)
- Analysis of the sequencer output

Snow leopard diet

Influence of the blocking primer during the DNA amplification

	feces 1		feces 2		feces 3	
<i>Uncia uncia</i>	74%	1%	97%	43%	100%	100%
<i>Capra sibirica</i>	26%	99%	0%	0%	0%	0%

Next generation sequencers and biodiversity

- Next generation sequencers
- The DNA barcoding concept
- High throughput plant identification
 - The *trnL* approach
 - Diet analysis of herbivores
 - Biodiversity assessment from environmental samples
- High throughput animal identification
 - Diet analysis of carnivores
 - Biodiversity assessment from environmental samples
- **Conclusion**

The "solexa" experiment

- A single run on the illumina/Solexa GS Iix sequencer
- Six months of preparation at the bench (more than 12,500 PCR products)
- Many experiments
 - Herbivore diet analysis (16 species)
 - Carnivore diet analysis (4 species)
 - Soil samples
 - Permafrost (plants)
 - Alpine soils (plants, earthworms)
 - Tropical soils (plants, earthworms, termites)
- 480,000,000 sequence reads of 108 nucleotides

DNA metabarcoding

- Works extremely well for diet analysis using feces as a source of DNA
 - For herbivores
 - For carnivores
 - Can be adjusted for other type of diet
- Works well for plant biodiversity using soil samples
 - In the Arctic
 - In the temperate region
 - In the tropical region
- Need to be further adjusted for animal biodiversity using soil samples
 - Optimistic for animals with high biomass (earthworms, etc.)
 - Might be problematic for animals with low biomass
